8 """
9 This script simulates the nonlinear pushover response of a single-degree-of-freedom system with a
10 contact/gap mechanism. The structure has a primary spring (elastic or hysteretic) that activates
11 immediately, while a secondary parallel spring engages only when displacement exceeds a specified
12 gap distance. This models structural components that come into contact only after certain
13 deformation thresholds, such as gap-opening in masonry infills, pounding between adjacent structures,
14 or secondary bracing systems activating during strong seismic events.
15
16 The analysis tracks force-displacement response, stiffness degradation, and period elongation
17 as damage accumulates. The eigenvalue analysis at each step captures how the natural period
18 increases with structural softening, a critical indicator of seismic vulnerability during
19 progressive damage. Contact activation causes a sudden stiffness increase when the gap closes,
20 followed by further period evolution as the system yields.
